00.exe ([SZfile]), with the same number and size as the original. The first couple of bytes have been modified to 0x55, the program seems to be waiting for an external event (an interrupt?) and, when the user presses any key, it immediately stops. I tried to terminate the task with Task Manager, but it was blocked forever. It seems it won't even return from the function it's calling (kernel32.CloseHandle(), as shown in the window's title bar), so there's no way to close it. I've looked for an answer for hours, but I've found nothing. Anyone knows what's happening or have any solution? I can't find the system log for Windows XP, so this is all I have. A: The only possible causes are: You are writing into a protected memory region that is only accessible through the kernel. If this is the case, call OutputDebugString and make sure it crashes with an exception. You are hooking into a kernel function. Call KeRaiseException and see if it crashes with an exception. Q: Is there a way to turn each element in an array into its own list? I have a list like this: list = ['1.0.0.0', '2.0.0.0', '3.0.0.0', '4.0.0.0', '5.0.0.0', '6.0.0.0', '7.0.0.0'] Is there a way to turn this list into a list of lists, like so: list_of_lists = [['1.0.0.0', '2.0.0.0', '3.0.0.0'], ['4.0.0.0', '5.0.0.0', '6.0.0.0'], ['7.0.0.0']] I'm currently using: list_of_lists = [[s for s in nd.split(',')] for nd in list] Which works, but seems messy. Try this: list_of_lists = [[n.strip() for n in s.split('.')[0]] for s in list] Correlates of HIV seroprevalence among injection 82157476af
